²Department of Energy, National Institute of Technology, Bhopal, India

Abstract: This paper presents an attempt of modeling a generalized Microalgae CO₂ Sequestration model using Matlab/Simulink software package, which can be representative for easy use on simulation platform. The proposed model is modeled in such a way with ease to user in handling and a dialog box like Simulink block libraries. This makes the generalized model easily simulated and analyzed in conjunction with power requirement for a maximum power utilized to cater the process of Sequestration at various levels. Taking the effect of solar Irradiance into consideration, the Micro-Algae growth kinetics and CO2 absorption rate of Sequestration model was simulated using the proposed model. This enables the dynamics of pilot plant system to be easily simulated, analyzed.

Keywords: Micro-Algae; CO₂ Sequestration, Solar Energy, MATLAB model.

Introduction:

With raising concerns about fuel deficit, hiking oil prices, global warming, and damage to ambient nature and ecosystem, there comes now promising incentives to develop alternative energy resources with high efficiency and low emission are of great importance. Among the renewable energy resources, the energy through the Solar effect can be considered the most essential and primary sustainable resource because of the abundance. Regardless of the intermittency of sunlight, solar energy is widely available and completely free of cost. Recently, solar energy in CO₂ Sequestration system by growing Micro bio-Algae species is likely recognized and widely utilized to the forefront in fuel utilities to extract oil out of populated algae in the raceways and open/closed photo bio-reactors. It can generate electricity without environmental impact and contamination when the oil is used in replacement of oil fired power stations, else the co firing of Algae residues in compliment to conventional coal fired power plants. Being biological systems, the Carbon sequestrating Solar System (CCSS) is static, quite, and free of moving parts, and these make it have little operation and maintenance costs. Even though the system is posed to its high capital fabrication cost and low conversion efficiency, the hiking oil prices make solar energy naturally viable energy supply with potentially long-term benefits. CCSS module represents the fundamental natural incubator unit of a bio-chemical system. The output characteristics of the module depend on the Solar Insolation, the CO₂ and assumed standard nutrients (nitrogen, phosphorus, potassium in sols). Since PV module has nonlinear characteristics, it is necessary to model it for the design and simulation of maximum output for various locality applications. The mathematical models used in computer simulation have been built for over the past four decades. However in MATLAB/Simulink package there is no CCSS model to integrate with simulation technology. Thus, it is difficult to simulate and analyze in the generic modeling of sequestration system. This motivates to develop a generalized model for Carbon sequestration using Simulink. The main contribution of this paper is the

implementation of a generalized model in the form of masked block, which has a user-friendly icon and dialog in the same way of Simulink block libraries or other component-based sub-system simulations.

Materials & Methods:

Algae farms on the use of open shallow ponds were CO2 emitted from the power plants are bubbled into the raceway ponds and utilized by algal strains growing the aqueous suspensions. The program targeted coal -fired power plants as the main sources of CO_2 . [1] In the traditional raceway design, culture depth and biomass concentrations have to be maintained low to ensure efficient penetration of sunlight. Large-scale raceways for algal cultivation have been operated with depths ranging from 30 to 50 cm. [2]

Figure 1: Sun, Water, Nutrients and CO2 input to raceway ponds [1] [3]

Figure 2: Array set-up of raceway ponds [1]

Here are in a position to estimate and model the Pond raceway's intake of various parameters especially sunlight (Photo synthetically active radiation-PAR), Yield of Algae, and auxiliary power consumptions that has to meet out in operating the raceway to maintain the yield as optimum.

i. Modeling of the Solar Insolation over the Micro Algae culture in Raceway:

The Insolation on the Culture depends upon the geometric position (demoted by latitude and longitude), which determines the site getting the interaction with sun (Solar Angle) and the time of the day (denoted by solar hour angle, declination, local solar time).

Figure 3: Model for Photosynthetically active Irradiance

Conclusion:

Micro Bio-Algal production systems with thermal power plants depends on several factors that were taken into account in this analysis: (1) PAR; (2) algal growth rate; (3) algal concentration in growth system; (4) energy requirement and, most importantly for India, (5) cost of the growth system. Based on current algal productivities alone, a large fraction of the CO₂ from the power plant could potentially be sequestered. Availability of PAR, favourable climatic conditions, adequate land demonstrates that raceway ponds may be the best method to cultivate algae. The assumptions made for this analysis are based on current techniques, productivities, and processes for mass algal cultivation. The recommendations revealed by this assessment are corroborated by the fact that, presently, nearly all algal biomass production facilities are operated in temperate or tropical locations. Despite the fact that algal biofuels may not yet be economically achievable in northern India, algae show great promise for the remediation of CO_2 point sources. Integrated CO_2 sequestration with power plants will, nonetheless, be an important step toward positive publicity of both CO_2 reduction and microalgal biomass production. Although biofuel production from microalgae in India is currently economically unfavorable, algae cultivation remains a very realistic goal provided certain key barriers to commercialization can be overcome. We believe that this work is best applied as a guide for areas of research and improvement required to allow algal production in conjunction with thermal power plant to become fully viable.
