Phytochemical Evaluation and Antibacterial Activity of Fruit Extract of *Solanum surattense* Burm F. against Some Pathogenic Bacteria

Edayathangudy G.S. Pillay College of Pharmacy, Nagapattinam, Tamil Nadu, India

**Abstract**: The objective of this study was to evaluate phytochemical constituents and antibacterial activity of hydroalcoholic extract of *Solanum surattense* fruit against some gram-positive and gram-negative bacterial strains. The evaluation of antibacterial activity was carried out by using the disc diffusion method, determination of minimum inhibitory concentration (MIC) and minimum bactericidal concentration (MBC). Ciprofloxacin was used as positive control. Hydroalcoholic extract of *Solanum surattense* fruit containing alkaloids, flavonoids, phenol, saponins, terpenoids, glycosides, sterols, proteins and tannins. Efficacy data analysis showed that hydroalcoholic extracts of fruit of *Solanum surattense* (1 mg/ml) inhibited the growth of *Staphylococcus aureus*, *Bacillus subtilis*, *Escherichia coli* and *Salmonella typhi* with mean diameters of inhibition zones being 24, 25, 28 and 30 mm respectively. On the other hand, minimum inhibitory concentration and minimum bactericidal concentration value of 0.062 and 0.25 mg/ml, 0.062 and 0.25 mg/ml, 0.312 and 0.125 mg/ml, 0.156 and 0.0312 mg/ml were recorded against *Staphylococcus aureus*, *Bacillus subtilis*, *Escherichia coli* and *Salmonella typhi* respectively. Hydroalcoholic extracts of *Solanum surattense* fruit have potent antibacterial activity against the different tested bacterial strains. This activity supports their use in treatment of infections caused by such resistant bacteria.

**Key words**: *Solanum surattense*, phytochemical analysis, antibacterial activity, Inhibition zones, MIC and MBC.

**Introduction**

For ages nature has gifted us plenty of herbs and plants which form the main source of traditional medicines used to help in relief from illness and are still widely used all over the world. Medicinal plants have been used for centuries as remedies for human diseases as they contain components of therapeutic value. There are numerous plant natural products which have antifungal, antibacterial and antiprotozoal activities that could be used either systemically or locally. Since earliest times, many plants have been known to exert healing properties against human infections due to their content of secondary metabolites, which in more recent times have been found to act as antimicrobial agents against human pathogens. Antibiotics are undeniably one of the
most important therapeutic discoveries of the 20th century that had effectiveness against serious bacterial infections. However, only one third of the infectious diseases known have been treated from these synthetic products. Antibiotic resistance has become a serious and widespread problem in developing countries, both in hospitals and the community, causing high mortality each year. Nevertheless, the discovery of new antibiotics is very expensive and time consuming, requiring about ten years to bring a new antibiotic to market. Therefore, the search for antibacterial substances derived from natural products, such as phytochemicals, has gained increasing importance alongside the discovery of new synthetic chemical compounds with antibiotic properties. Solanum surattense (Solanaceae) is frequently used in Indian traditional medicine for curing various ailments such as respiratory diseases, gonorrhoea, rheumatism, fever and asthma. Solanums uratatense is widely spread throughout India in dry situation as abundant by road sides and wastelands. It is essentially a warm season crop grown mainly in tropical and sub-tropical regions. The plant is useful in fever, cough, asthma and pain in chest, being used in the form of decoction or electuary. The fruit and leaf extract possess significant antihyperglycemic activity. The aim of this study was to screen the in vitro antibacterial activity of fruit of Solanum surattense against some Gram-positive and Gram-negative bacterial strains.

Material and Methods

Collection and identification of plants materials:

The fruits of Solanum surattense were used for the study. It was collected from Tiruvarur district, Tamil nadu during the month of March and April. The plant materials were taxonomically identified and authenticated by Dr.S. JOHN BRITTO., Director, The Rapinat Herbarium Centre for Molecular Systematic, St. Joseph’s college (campus) Tiruchirappalli-620 002, Tamil Nadu, India. The plant was thoroughly washed in running tap water to remove soil particles and adhered debris and finally washed with distilled water. The fruits of the plant alone were segregated and dried under shade, pulverized by a mechanical grinder into fine powder. The powdered materials were stored in air tight polythene bags till use.

Preparation of extracts:

The powdered plant materials of Solanum surattense fruits were subjected to hydroalcoholic extraction in the ratio of water: ethanol as 30:70. The extraction was done by hot continuous percolation method in Soxhlet apparatus for 24 hrs. The extract was concentrated by using a rotary evaporator till dry powder was obtained.

Percentage yield for the hydroalcoholic extract of Solanum surattense fruits

The percentage yield for the hydroalcoholic extract of fruits of Solanum surattense was calculated with reference to air dried powdertaken using the formula given below.

\[
\text{Percentage yield} = \frac{\text{Weight in grams of extracts obtained}}{\text{Weight in grams of plant materials taken}} \times 100
\]

Preliminary phytochemical screening:

Preliminary phytochemical screening was conducted on hydroalcoholic extract of fruits of Solanum surattense to determine the different phytochemical constituents present in the extracts.

Thin-layer Chromatographic Studies (TLC):

Thin-layer chromatography was carried out on hydroalcoholic extract of fruits of Solanum surattense using a sheet of aluminium foil which is coated with a thin layer of adsorbent silica gel, which are commercially available 60 F254 (Merck). The plates were cut with scissorsand marked with pencil about 2cm from the bottom of the plate. TLC is performed on Samples prepared with different solvents were spotted onto the TLC plate as a single spot with capillary tubes. TLC plates were viewed in UV chamber at both 254 nm and 365 nm. The movement of the analyse was expressed by its retention factor (Rf).
Distance travelled by solute

\[ \text{Rf value} = \frac{\text{Distance travelled by solute}}{\text{Distance travelled by solvent}} \]

Anti-bacterial activity of *Solanum surattense* fruit extracts

**Bacterial strains**

The antibacterial potency of plant extract was evaluated using four bacterial strains. Two strains of Gram-positive bacteria (*Staphylococcus aureus* and *Bacillus subtilis*) and two strains of Gram-negative bacteria (*Escherichia coli* and *Salmonella typhi*). These microorganisms were collected from CSIR-National Chemical Laboratory, Dr. Homi Bhabha Road, Pune- 411 008, India.

**Inoculums preparation:**

Each bacterial strain was subcultured overnight at 35°C in Mueller-Hilton agar slants. The bacterial growth was harvested using 5 ml of sterile saline water; its absorbance was adjusted at 580 nm and diluted to attain viable cell count of 10⁷ CFU/ml using spectrophotometer.

**A. Disk diffusion method**:\(^1\)

The disk diffusion method is used to evaluate antimicrobial activity of the plant extract. The plant extract residues (1 mg) were re-dissolved in 0.5% DMSO (5ml DMSO make up to 100ml with water), sterilized through Millipore filter (0.22 µm) then loaded over sterile filter paper discs (8 mm in diameter) to obtain final concentration of 1 mg/ml. Ten ml of Mueller-Hilton agar medium was poured into sterile Petri dishes (as a basal layer) followed with 15 ml of seeded medium previously inoculated with bacterial suspension to attain 10⁶ CFU/ml of medium. Sterile filter paper discs loaded with plant extract concentration of (1 mg/ml) were placed on the top of Mueller-Hilton agar plates. Filter paper discs loaded with 30µg of ciprofloxacin was used as positive control. The plates were kept in the fridge at 5°C for 2 h. to permit plant extracts diffusion then incubated at 35°C for 24 h. The presence of inhibition zones was measured by Vernier calliper recorded and considered as indication for antibacterial activity.

**B. Determination of MIC and MBC values**:\(^2\)

Using aseptic techniques, a single colony was transferred into a 100mL bottle of isosensitest broth capped and placed in incubator overnight at 35°C. After 12–18 h of incubation, using aseptic preparation and the aid of a centrifuge, a clean sample of bacteria was prepared. The broth was spun down using a centrifuge set at 4000 rpm for 5 min with appropriate aseptic precautions. The supernatant was discarded into an appropriately labelled contaminated waste beaker. The pellet was resuspended using 20mL of sterile normal saline and centrifuged again at 4000 rpm for 5 min. This step was repeated until the supernatant was clear. The pellet was then suspended in 20mL of sterile normal saline, and was labelled as Bs. The optical density of the Bs was recorded at 500 nm, and serial dilutions were carried out with appropriate aseptic techniques until the optical density was in the range of 0.5–1.0. The actual number of colony-forming units was calculated from the viability graph. The dilution factor needed was calculated and the dilution was carried out to obtain a concentration of 5×10⁶ CFU/mL.

**Preparation of resazurin solution**

The resazurin solution was prepared by dissolving a 270mg tablet in 40mL of sterile distilled water. A vortex mixer was used to ensure that it was a well-dissolved and homogenous solution.

**Preparation of Microtitre plates**

Microtitre plates were prepared under aseptic conditions. A germ-free 96 well plate was labelled. First row of the plate was poured with test materials (100 µl) in 10% (v/v) DMSO or sterile water. Remaining all wells were poured with 50 µL of nutrient broth or normal saline. To each well 10 µL of resazurin indicator
solution was added. 30 µl of 3.3x strength isosensitised broth was added individually to each well to ensure that the final volume was single strength of the nutrient broth. Finally, 10 µL of bacterial suspension (5×106 CFU/mL) was added to each well to attain a concentration of 5×106 CFU/mL. All plates were incubated at 37 °C for 18–24 h. Colour changes from purple to pink or colourless was noted. MIC Value were recorded from the lowest concentration at which colour changes. Different concentration of sample solution was streaked in petridish containing nutrient broth and incubated at 35°C for 24h. Lowest concentration that gave no visible growth was recorded as minimum bactericidal concentration (MBC).

Results

Percentage yield

The percentage yield for the hydroalcoholic extract of Solanum surattense fruit was calculated. Percentage yield was found to be 11.66 %w/w

Preliminary phytochemical screening

Preliminary phytochemical screening for the hydroalcoholic extract of Solanum surattense fruit was carried out and the results are tabulated in Table 1. The hydroalcoholic extract of Solanum surattense fruit containing alkaloids, flavonoids, phenol, saponins, terpenoids, glycosides, sterols, proteins and tannins.

Anti-bacterial activity of *Solanum surattense* fruit extracts

**A. The disk diffusion method**

Antibacterial activity of hydroalcoholic extracts of *Solanum surattense* fruit (1 mg/ml) was employed by disc diffusion method to evaluate their bacteriostatic and bactericidal properties. Effect of the effective plant extract was reported in Table 3 and illustrated in Fig. 3a and 3b. Efficacy data analysis showed that hydroalcoholic extracts of fruit of *Solanum surattense* (1 mg/ml) inhibited the growth of *Staphylococcus aureus*, *Bacillus subtilis*, *Escherichia coli* and *Salmonella typhi* with mean diameters of inhibition zones being 24, 25, 28 and 30 mm respectively.

**Determination of MIC and MBC values**

Minimum inhibitory concentration and minimum bactericidal concentration value have been determined with *Solanum surattense* fruit extracts (1 mg/ml)(Fig. 4). MIC and MBC value of 0.062 and 0.25 mg/ml, 0.062 and 0.25 mg/ml, 0.312 and 0.125 mg/ml and 0.156 and 0.0312 mg/ml were recorded against *Staphylococcus aureus*, *Bacillus subtilis*, *Escherichia coli* and *Salmonella typhi* respectively (Table 4).

Discussion

Research for new antibacterial agents has become a very important endeavour, especially in recent times, considering the escalating levels of antibiotic resistance among pathogenic bacteria. One of the efforts in this research is focused on the use of medicinal plants, which are widely available resources, less if no side effects, less expensive and have shown antimicrobial properties. Preliminary phytochemical analyses revealed that hydroalcoholic extract of *Solanum surattense* fruit containing alkaloids, flavonoids, phenol, saponins, terpenoids, glycosides, sterols, proteins and tannins. These bioactive compounds have been reported to be used by plants for protection against bacterial and are responsible for antimicrobial activity. Thin layer chromatography is usually done for a better identification of the bioactive compounds. In the present study the TLC profiling of plant extract again revealed the presence of different metabolites such as alkaloids, flavonoids, glycosides, phenols, and tannins. Agar well diffusion method and MIC value has been used by many investigators to find out the antimicrobial activity of the test compounds. Results of antimicrobial activity of the hydroalcoholic extracts of *Solanum surattense* fruit can suggested that *Staphylococcus aureus, Bacillus subtilis, Escherichia coli* and *Salmonella typhi* were most susceptible strains to the extract and showed strong antibacterial activity. Hence, experiments were conducted to determine their minimal inhibitory concentration (MIC) and minimal bactericidal concentration (MBC) against the most susceptible bacterial strains. In the present study the MIC value of the active plant extracts obtained in this study were lower than the MBC values suggesting that the plant extracts were bacteriostatic at lower concentration but bactericidal at higher concentration.
Conclusion

The result of this study showed that hydroalcoholic extracts of *Solanum surattense* fruits have potential antimicrobial components that may be definitely used as a therapy against various disease by the pharmaceutical industries. However, further studies are needed, including toxicity evaluation and purification of active antibacterial constituents from *Solanum surattense* extracts looking toward a pharmaceutical use.

Acknowledgement

The authors express their deep sense of gratitude to Prof. Dr. D. Babu Ananth Principal, E.G.S. Pillay College of Pharmacy, Tamil Nadu and India for providing all the supports and encouragement in conducting the research work.
