# Novel metal complexes of guanidine ligand; Synthesis, Spectroscopic Characterization and Biological Activity 

Abdou Saad El-Tabl ${ }^{1 *}$, Joseph Jimmy Stephanos ${ }^{1}$,<br>Moshira Mohamed Abd-Elwahed ${ }^{2}$ and Sabreen Mohamed El-Gamasy ${ }^{1}$<br>${ }^{1}$ Department of Chemistry, Faculty of Science, El-Menoufia University, Shebin El-Kom, Egypt.<br>${ }^{2}$ Department of Pathology, Faculty of Medicine, El-Menoufia University, Shebin El-Kom, Egypt.

#### Abstract

Metal complexes of N- (amino [2- hydroxy] methylene) amino - methylene - carbono ctra of solid $\mathrm{Cu}($ II $)$ complexes show axial type symmetry with $\mathrm{g}_{/ /}>\mathrm{g}_{\perp}>2.00$, indicating a $\mathrm{d}_{(x 2-y 2)}$ ground state with significant covalent bond character, The spectrum of $\mathrm{Cu}(\mathrm{II})$ complex (2) $\left[(\mathrm{L})_{2}(\mathrm{Cu})_{2}(\mathrm{OAc})_{2}\right] \cdot 3 \mathrm{H}_{2} \mathrm{O}$ is a characteristic of a triplet state of a dimmer species and the distance found between the two $\mathrm{Cu}(\mathrm{II})$ centers is $4.2 \mathrm{~A}^{\circ}$. Complexes showed chemotherapeutic effects where they showed inhibitory effect on hepatocellular carcinoma (HepG- 2 cell line) in comparing with the standard drug.

Key words: Metal complexes, Guanidine ligand, Synthesis, Spectroscopic Characterization, Biological Activity.

## Introduction

Growing interest in guanidinum Schiff base stems from their potential applications in the field of chelating chemistry. Guanidiniums are very weakly acidic molecules with the capacity to form intermolecular contacts mediated by H-bonding interactions ${ }^{1}$. The guanidinium moiety is common in natural products ${ }^{2}$ and is often used in molecular recognition ${ }^{3}$. They also play important biological roles ${ }^{4,7-11}$. Various methods exist for the synthesis of guanidiniums from different starting materials and reagents ${ }^{5}$. One of the well-known methods is the conversion of thioureas into guanidiniums in the presence of a coupling reagent ${ }^{6}$. The conversion of thioureas into guanidiniums is usually accomplished with an electron withdrawing protecting group on the thiourea, that are not only capable of facile deprotection, but also activate the thiourea for the coupling reaction. Most thioureas that contain these activating groups can be only coupled with primary amines. Furthermore, the efficiency of guanylation depends on the group attached to the primary amine. Thioureas mostly react with primary amines attached to primary carbons due to the bulkiness of the protecting groups. Amines attached to electron withdrawing groups tend to give lower yields in guanylation. Recent advances have demonstrated the importance of the guanidinum group in receptors capable of binding molecular anions ${ }^{7,8}$. A number of reviewed articles had been reported dealing with coordination chemistry of guanidinum derivatives, which has reflected great attention during the last years from avariety of reasons including as antitumer agent ${ }^{9,10}$ green corrosion inhibitor for mild acidic solution ${ }^{11}$, anti-glaucouma and cardiotonic derivatives, and for synthesis of polymer types ${ }^{12,13}$. Guanidinum groups serve as anion-building fragments in designed superamolecular receptors ${ }^{7,8}$, used to improve insulin sensitivity ${ }^{14}$ and to promote weight loss

[^0]selectivity from a dipose tissue in animal models of non-insulin dependent diabetes mellitus ${ }^{14}$. Also, guanidinum derivatives affect on the mitochondrial function in the cell ${ }^{15}$, in mineralization of guanidinum derivatives in soils ${ }^{16}$. The guanidinium ion also participates in numerous enzymatic transformations, as it is able to adopt a transition state assembly with the substrates to reduce the activation energy or to stabilize anionic intermediates, and is able to orient specific substrates based on their electronic properties ${ }^{17}$.
Complexes of Schiff base (Figure 1) had been synthesized and characterized using different physical tools and the complexes have square planar or octahedral structure ${ }^{18,19}$. Boghaei ${ }^{20}$ synthesized and investigated non-symmetrical tetradentate Schiff base complexes of nickel(II) and copper(II) ions. Some unsymmetrical diimino tetradentate Schiff bases derived from 3,4-diaminobenzophenone,(N-salicyliden-N'-5-OMe.salycyliden)-3,4-diaminobenzophenone ( $\mathrm{H}_{2}$ sal-5-OMe.sal.dabp) ( $\mathrm{H}_{2} \mathrm{~L}_{1}$ ), ( $\mathrm{H}_{2}$ sal-5-Br.sal.dabp) $\left(\mathrm{H}_{2} \mathrm{~L}_{2}\right)$, ( $\mathrm{H}_{2}$ sal-5-Cl.sal.dabp) $\left(\mathrm{H}_{2} \mathrm{~L}_{3}\right)$ and $\left(\mathrm{H}_{2}\right.$ sal-5- $\mathrm{NO}_{2}$.sal.dabp) $\left(\mathrm{H}_{2} \mathrm{~L}_{4}\right)$ and their nickel(II) and copper(II) complexes were synthesized and characterized by elemental and spectral analyses ${ }^{21}$. Zinc(II), nickel(II) and copper(II) complexes of Schiff base, synthesized by condensation of o- vanilline with allyl thiourea have been prepared and spectroscopically characterized ${ }^{22}$.

Figure (1)

Complexes with the general formula $\mathrm{MX}_{2}(\mathrm{hppH})_{2}$, [hppH $=1,3,4,6,7,8-$ hexahydro- 2 H - pyrimido]. Pyrimidine, have been synthesized and structurally characterized ${ }^{23}$.
Due to guanidine ligands importance, we reported, synthesis, spectroscopic characterization and cytotoxic effect of new ligand N - (amino [2- hydroxy] methylene) amino - methylene - carbono hydrazonic diamide Ligand and its metal complexes.

## Experimental

Materials
All the reagents were of the best grade available and used without further purification.

## Physical measurements

$\mathrm{C}, \mathrm{H}, \mathrm{N}$ and Cl analyses were determined at the Analytical Unit of Cairo University, Egypt. A standard gravimetric method was used to determine metal ion ${ }^{24}$. All metal complexes were dried under vacuum over $\mathrm{P}_{4} \mathrm{O}_{10}$. The IR spectra were measured as KBr and CeBr pellets using a Perkin-Elmer 683 spectrophotometer ( $4000-200 \mathrm{~cm}^{-}$ ${ }^{1}$ ). Electronic spectra (qualitatively) were recorded on a Perkin-Elmer 550 spectrophotometer. The conductance of $10^{-3} \mathrm{M}$ solutions of the complexes in DMF were measured at $25^{\circ} \mathrm{C}$ with a Bibby conductimeter type MCl. ${ }^{1} \mathrm{H}-\mathrm{NMR}$ spectra (ligand and its Cd (II) complex) were obtained with Perkin-Elmer R32-90-MHz spectrophotometer using TMS as internal standard. Mass spectrum of the ligand was recorded using JEULJMS-AX-500 mass spectrometer provided with data system. The thermal analyses (DTA and TGA) were carried out in air on a Shimadzu DT-30 thermal analyzer from 27 to $800^{\circ} \mathrm{C}$ at a heating rate of $10^{\circ} \mathrm{C}$ per minute. Magnetic susceptibilities were measured at $25^{\circ} \mathrm{C}$ by the Gouy method using mercuric tetrathiocyanato cobalt(II) as the magnetic susceptibility standard. Diamagnetic corrections were estimated from Pascal's constant ${ }^{25}$. The magnetic moments were calculated from the equation: $\mu_{\text {eff }}=2.84 \sqrt{\chi_{M}^{\text {corr }} \cdot T}$. The ESR spectra of solid complexes at room temperature were recorded using a varian E-109 spectrophotometer, DPPH was used as a standard material. The T.L.C of all compounds confirmed their purity.

## Preparation of the ligand and its metal complexes

## Preparation of the ligand, [HL], (1)

Ligand (1) was prepared by refluxing thiourea ( $20 \mathrm{gm}, 0.3228 \mathrm{~mol}$ ) and hydrazine hydrate ( $8 \mathrm{gm}, 0.16 \mathrm{~mol}$ ) in ethanol $\left(100 \mathrm{~cm}^{3}\right)$ for 2 hours with stirring. Cool the product at room temperature and filter it to separate the hydrazide. Salicaldhyde ( $8.42 \mathrm{gm}, 0.0689 \mathrm{~mol}$ ) was added to the hydrazide crystals ( $8 \mathrm{gm}, 0.0689 \mathrm{~mol}$ ) and refluxed with stirring for 2 hours, the yellow precipitate was filtered off, washed by ethanol several times and dried in vaccum over $\mathrm{P}_{4} \mathrm{O}_{10}$. Analytical data are given in Table 1.

Synthesis of metal complexes (2) - (19)
To the ligand (1) ( $5.0 \mathrm{gm}, 0.0171 \mathrm{~mol}$ ) in ethanol $\left(50 \mathrm{~cm}^{3}\right)$ was added to $\left(30 \mathrm{~cm}^{3}\right)$ ethanolic solution of ( $3.417 \mathrm{gm}, 0.0171 \mathrm{~mol}$ ) of $\mathrm{Cu}(\mathrm{OAc})_{2} \cdot \mathrm{H}_{2} \mathrm{O}$, ( $1 \mathrm{~L}: 1 \mathrm{M}$ ), complex (2), ( $2.302 \mathrm{gm}, 0.0171 \mathrm{~mol}$ ) of $\mathrm{CuCl}_{2} .2 \mathrm{H}_{2} \mathrm{O}$, (1L:1M), complex (3), ( $2.73 \mathrm{gm}, 0.0171 \mathrm{~mol}$ ) of $\mathrm{CuSO}_{4} .5 \mathrm{H}_{2} \mathrm{O}(1 \mathrm{~L}: 1 \mathrm{M})$, complex (4), ( $4.135 \mathrm{gm}, 0.0171 \mathrm{~mol}$ ) of $\mathrm{Cu}\left(\mathrm{NO}_{3}\right)_{2} .3 \mathrm{H}_{2} \mathrm{O},(1 \mathrm{~L}: 1 \mathrm{M})$, complex (5), (4.26 gm, 0.0171 mol$)$ of $\mathrm{Ni}(\mathrm{OAc})_{2} .4 \mathrm{H}_{2} \mathrm{O},(1 \mathrm{~L}: 1 \mathrm{M})$, complex (6), ( 4.26 gm , $0.0171 \mathrm{~mol})$ of $\mathrm{Co}(\mathrm{OAc})_{2} .4 \mathrm{H}_{2} \mathrm{O},(1 \mathrm{~L}: 1 \mathrm{M})$, complex (7), ( $4.195 \mathrm{gm}, 0.0171 \mathrm{~mol}$ ) of $\mathrm{Mn}(\mathrm{OAc})_{2} .4 \mathrm{H}_{2} \mathrm{O},(1 \mathrm{~L}: 1 \mathrm{M})$, complex (8), ( $3.755 \mathrm{gm}, 0.0171 \mathrm{~mol}$ ) of $\mathrm{Zn}(\mathrm{OAc})_{2} .2 \mathrm{H}_{2} \mathrm{O},(1 \mathrm{~L}: 1 \mathrm{M})$, complex (9), ( $4.562 \mathrm{gm}, 0.0171 \mathrm{~mol}$ ) of $\mathrm{Cd}(\mathrm{OAc})_{2} .2 \mathrm{H}_{2} \mathrm{O},(1 \mathrm{~L}: 1 \mathrm{M})$, complex (10), ( $7.259 \mathrm{gm}, 0.0171 \mathrm{~mol}$ ) of $\mathrm{UO}_{2}(\mathrm{OAc})_{2} .2 \mathrm{H}_{2} \mathrm{O},(1 \mathrm{~L}: 1 \mathrm{M})$, complex (11), $(5.454 \mathrm{gm}, 0.0171 \mathrm{~mol})$ of $\mathrm{Hg}(\mathrm{OAc})_{2},(1 \mathrm{~L}: 1 \mathrm{M})$, complex (12), $(4.508 \mathrm{gm}, 0.0171 \mathrm{~mol})$ of $\mathrm{Tl}(\mathrm{OAc}),(1 \mathrm{~L}: 1 \mathrm{M})$, complex (13), ( $4.626 \mathrm{gm}, 0.0171 \mathrm{~mol}$ ) of $\mathrm{FeCl}_{3} .6 \mathrm{H}_{2} \mathrm{O}$, ( $1 \mathrm{~L}: 1 \mathrm{M}$ ), complex (14), ( $4.561 \mathrm{gm}, 0.0171 \mathrm{~mol}$ ) of $\mathrm{CrCl}_{3} .6 \mathrm{H}_{2} \mathrm{O}$, ( $1 \mathrm{~L}: 1 \mathrm{M}$ ), complex (15), ( $5.516 \mathrm{gm}, 0.0171 \mathrm{~mol}$ ) of $\mathrm{ZrOCl}_{2} .8 \mathrm{H}_{2} \mathrm{O}$, ( $1 \mathrm{~L}: 1 \mathrm{M}$ ), complex (16), ( 2.516 gm , 0.0171 mol ) of $\mathrm{CaCl}_{2} \cdot 2 \mathrm{H}_{2} \mathrm{O}$, ( $1 \mathrm{~L}: 1 \mathrm{M}$ ), complex (17), ( $4.563 \mathrm{gm}, 0.0171 \mathrm{~mol}$ ) of $\mathrm{SrCl}_{2} .8 \mathrm{H}_{2} \mathrm{O}$, ( $1 \mathrm{~L}: 1 \mathrm{M}$ ), complex (18) and ( $2.909 \mathrm{gm}, 0.0171 \mathrm{~mol}$ ) of $\mathrm{AgNO}_{3}$, ( $1 \mathrm{~L}: 1 \mathrm{M}$ ), complex (19). The mixture was refluxed with stirring for 2-4 hrs , depending on the nature of the metal ion and the anion. When the precipitate appeared, it was removed by filteration, washed with ethanol and dried in vacuo over $\mathrm{P}_{4} \mathrm{O}_{10}$. Analytical data are given in Table 1.

## Biological activity

The Chemotherapeutic effect was measured invitro for the synthesized complexes using the Sulfo Rhodamine-B-stain (SRB) assay using the puplished methods ${ }^{26}$. Cells were plated in 96 -multiwell plate $\left(10^{4}\right.$ cells/well) for 24 hrs before treatment with the compounds to allow attachment of cell to the wall of the plate. Different concentrations of the compound in DMSO under test ( $0,1.56,3.125,6.5,12.5$ and $25 \mu \mathrm{~g} / \mathrm{ml}$ ) were added to the cell monolayer triplicate wells were prepared for each individual dose. Monolayer cells were incubated with the compounds for 48 hrs at $37^{\circ} \mathrm{C}$ and in atmosphere of $5 \% \mathrm{CO}_{2}$. After 48 hrs , Cells were fixed, washed and stained with Sulfo-Rhodamine-B-stain. Excess stain was wash with acetic acid and attached stain was recovered with Tris EDTA buffer ( $10 \mathrm{mMTrisHCl}, 1 \mathrm{mM}$ disoduim EDTA, $\mathrm{pH}=7.5-8$ ). Color intensity was measured in an ELISA reader. The relation between surviving fraction and drug concentration, is plotted to get the survival curve of each tumor cell line after the specified compound.

## Result and discussion

The analytical and physical data (Table 1), spectral data (Tables 2 and 3) reveal that, the complexes are formed in (1:1) or (1:2) (M: L) stiochiometric ratio. All the complexes are stable at room temperature, insoluble in common solvents, viz: $\mathrm{MeOH}, \mathrm{EtOH}, \mathrm{CHCl}_{3}, \mathrm{CCl}_{4}$ and $\left(\mathrm{CH}_{3}\right)_{2} \mathrm{CO}$ but soluble in $\mathrm{DMSO}^{24,}{ }^{25}$. Ligand (1), was synthesized by condensation of tetraamine with salicaldhyde (1:1) - (1:3), molar ratios as shown in Figure (2).

We notice that, (1:1) or (1:2) or (1:3) molar ratios of tetraamine with salicaldhyde give ligand (1), may be due to the formation of strong hydrogen bondings or steric effect. The proposed structures of the complexes are shown in Figure (3). Scheme (1) illustrates that, the composition of the complexes formed depends on metal salts, the medium of the reaction and the molar ratios.

## Mass spectrum of the ligand, (1)

The mass spectrum of the ligand supported, the suggested structure, Figure (2) revealing a molecular ion peak $(\mathrm{m} / \mathrm{z})$ at 294.1, coincident with the molecular weight of the ligand. Morever, the fragmentation pattern splits a parent ion peak at $(\mathrm{m} / \mathrm{z})=67$ a.m.u. corresponding to $\mathrm{C}_{2} \mathrm{HN}_{3}$ while the fragments at $(\mathrm{m} / \mathrm{z})=121,135,207$ and 222 a.m.u. 84, 93 correspond to $\mathrm{C}_{2} \mathrm{H}_{4} \mathrm{~N}_{4}, \mathrm{C}_{6} \mathrm{H}_{5} \mathrm{O}, \mathrm{C}_{7} \mathrm{H}_{7} \mathrm{~N}_{2} \mathrm{O}, \mathrm{C}_{8} \mathrm{H}_{11} \mathrm{~N}_{6} \mathrm{O}$ and $\mathrm{C}_{9} \mathrm{H}_{12} \mathrm{~N}_{6} \mathrm{O}$, respectively (Table 1).

## ${ }^{1} \mathrm{H}$ - NMR spectra

The ${ }^{1} \mathrm{H}$ - NMR spectra of ligand and its cadmium(II) complex (10) in deuterated DMSO show signals consistent with the proposed structure. The peak at 11.3 p.p.m is due to proton of OH group ${ }^{28}{ }^{28}$. The signals observed at 3.42 and 2.5 p.p.m, are due to the protons of $\mathrm{NH}_{2}$ group ${ }^{30}$. The azomethine proton of $\mathrm{CH}=\mathrm{N}$ group appears at 9.1 p.p.m ${ }^{28,31}$. The peaks observed as multiple ones at $6.0-7.7$ p.p.m may be assigned to aromatic protons ${ }^{28}$. The spectrum of cadmium(II) complex (10) shows, the protons of $\mathrm{NH}_{2}$ group at 3.32 and 2.49 p.p.m and the signal characteristic to the phenolic hydroxyl group $(\mathrm{OH})$ appeared in the same position of the ligand, indicating that, the hydroxyl group did not participate in the coordination ${ }^{28}$. Complexation leads to a significant downfield shift of the azomethine proton ( 8.9 p.p.m) relative to the free ligand confirms that, the azomethine nitrogen atom coordinates to the metal $(\mathrm{N}-\mathrm{Cd})^{28}$. The aromatic protons appear in the 6.1-8.0 p.p.m range ${ }^{31}$. A new signal was observed at 1.84 p.p.m which may be assigned to the protons of the coordinated acetate group ${ }^{31,32}$.

## Conductivity

The molar conductance values of the complexes in DMF $\left(10^{-3} \mathrm{M}\right)$ lie in the $22-11 \mathrm{~mol}^{-1} \mathrm{~cm}^{2}$ range (Table 1), indicating that, all the complexes are not electrolytes ${ }^{27,33}$. This confirms that, the anion is coordinated to the metal ion.

## IR spectra

The modes of bonding between the ligand and the metal ion can be revealed by comparing the IR spectra of the solid complexes with that of the ligand. The IR spectral data of the ligand and its metal complexes are presented in Table 2. The IR spectrum of the ligand shows broad medium bands in the $3600-3200$ and $3180-2950 \mathrm{~cm}^{-1}$ ranges, attributed to intra- and intermolecular hydrogen bonds between aromatic OH or $-\mathrm{NH}_{2}$ with $\mathrm{C}=\mathrm{N}$ groups ${ }^{34,35}$. Thus, the higher frequency band is associated with a weaker hydrogen bond and the lower frequency band with a stronger hydrogen bond. The spectrum also shows bands at 3407 and 3316 and $3275 \mathrm{~cm}^{-1}$, assigned to the stretching vibrations of the phenolic hydroxyl $v(\mathrm{OH})$ and amino $v\left(\mathrm{NH}_{2}\right)$ associated through intermolecular and intramolecular hydrogen bondings ${ }^{28,36,37}$. The relatively strong bands located at $1617,1266,1031$ and $1546 \mathrm{~cm}^{-1}$ are assigned to the $v(\mathrm{C}=\mathrm{N})$ imine, $v(\mathrm{OH}), \quad v(\mathrm{~N}-\mathrm{N}), v(\mathrm{C}=\mathrm{C})_{\mathrm{Ar}}$ respectively ${ }^{28}$. A broad band appears in the $3500-3220 \mathrm{~cm}^{-1}$ range corresponds to the hydrated water molecules ${ }^{38}$. In all complexes, the band due to azomethine $v(\mathrm{C}=\mathrm{N})_{\text {imine }}$ was shifted with decreasing its intensity indicating its coordination to the central metal ion ${ }^{28,39}$. The $v\left(\mathrm{NH}_{2}\right)$ and $v(\mathrm{OH})$ groups appear in the $3430-3230$ and $3430-3376 \mathrm{~cm}^{-1}$ ranges $^{40,41}$ and $v(\mathrm{~N}-\mathrm{N})$ group observed in the 1028-1015 $\mathrm{cm}^{-1}$ range which are shifted to lower frequency compared to the ligand. The $v(\mathrm{C}=\mathrm{C})_{\text {Ar }}$ appears in the $1580-1530$ and $766-744 \mathrm{~cm}^{-1}$ ranges ${ }^{40,41}$. The complexes show broad bands in the $3650-2900$ and $3270-2650 \mathrm{~cm}^{-1}$ ranges except complexes (12) and (13), assigned to the presence of hydrated or coordinated water molecules ${ }^{40}$. However, the bands appear in the $3600-2920$ and $3190-2500 \mathrm{~cm}^{-1}$ ranges, are due to intra- and intermolecular hydrogen bondings ${ }^{28,36,37}$. New bands in the $616-501$ and $488-434 \mathrm{~cm}^{-1}$ ranges were taken as indication of coordination
between the metal ions with oxygen and nitrogen atoms ${ }^{39,40}$. Complexes (3)-(13), (16) - (19) show bands in the $3430-3376 \mathrm{~cm}^{-1}$ ranges are due to $v(\mathrm{OH})$ group [44]. Complex (4) shows bands at $1120,1028,898,685$ and $464 \mathrm{~cm}^{-1}$ due to the coordinated monodentate sulphate group ${ }^{45}$. Extensive IR spectral studies reported on metal acetate complexes ${ }^{42}$ indicate that, the acetate ligand coordinates ${ }^{39}$ in either a monodentate, bidentate or bridging manner, the $v_{\mathrm{a}}\left(\mathrm{CO}_{2}\right)$ and $v_{\mathrm{s}}\left(\mathrm{CO}_{2}\right)$ of the free acetate are at 1560 and $1416 \mathrm{~cm}^{-1}$ respectively. In monodentate, coordination $v(\mathrm{C}=\mathrm{O})$ is at higher energy than $v_{\mathrm{a}}\left(\mathrm{CO}_{2}\right)$ and $v(\mathrm{C}-\mathrm{O})$ is lower than $v_{\mathrm{s}}\left(\mathrm{CO}_{2}\right)$. As a result, the separation between $v(\mathrm{CO})$ bands is much larger in monodentate complexes. In complexes (6) - (13), the bands is due to $v_{\mathrm{a}}\left(\mathrm{CO}_{2}\right)$ appeared in the $1545-1480 \mathrm{~cm}^{-1}$ and the $v_{\mathrm{s}}\left(\mathrm{CO}_{2}\right)$ observed in the $1440-1346 \mathrm{~cm}^{-1}$ ranges. The difference between these two bands is in the $160-103 \mathrm{~cm}^{-1}$ range, suggesting that, the acetate group coordinates in unidentate manner with the metal ions ${ }^{28}$. However, bridging acetate group with both oxygen atoms coordinated (as in copper(II) acetate) have $v(\mathrm{CO})$ bands close to the free ion values ${ }^{28,46}$ as found for complex (2), $v_{\mathrm{a}}\left(\mathrm{CO}_{2}\right)=1570$ and $v_{s}\left(\mathrm{CO}_{2}\right)=1420 \mathrm{~cm}^{-1}$. A new band observed in the $440-410 \mathrm{~cm}^{-1}$, may be assigned to $v(\mathrm{M}-\mathrm{Cl})$ in the chloro complexes (14) - (18) ${ }^{47}$. Complexes (5) and (19) show bands at 1386, 1273, 827 and 785 and 1386, 1198, 840 and $765 \mathrm{~cm}^{-1}$ respectively, assigned to coordinated nitrate group ${ }^{34,38}$. The complex (19) has a monomeric trigonal planar in which the guanidine coordinates as a pseudo- bidentate ligand interacting with silver ion and nitrate group via $\mathrm{N}_{\mathrm{imine}}$ and NH moieties ${ }^{23}$. The complexes show $v(\mathrm{OH})$ band in the $1306-1270 \mathrm{~cm}^{-1}$, except complexes (2), (14) and (15) show $v(\mathrm{CO})$ band at 1198,1199 and $1201 \mathrm{~cm}^{-1}$ respectively ${ }^{38,48}$. The appearance of $v(\mathrm{OH})$ group at higher wave number comparing to the ligand ( $1266 \mathrm{~cm}^{-1}$ ), indicating non- coordinated of this group to the metal ion. However, complexes (2), (14) and (15) show bands at lower wave number (Table 2) indicating deprotonated of the OH group due to coordination to the metal ion. Complex (11) shows band at $885 \mathrm{~cm}^{-1}$ due to $\mathrm{O}=\mathrm{U}=\mathrm{O}^{49}$, however, complex (16) shows a band at $848 \mathrm{~cm}^{-1}$, assigned to $v(\mathrm{ZrO})$ vibration ${ }^{50}$.

## Magnetic moments

The room temperature magnetic moments of the complexes (2) - (19) are shown in Table (3). Copper(II) complexes (3), (4) and (5) show values $1.76,1.75$ and 1.68 B.M., corresponding to one unpaired electron in an octahedral structure ${ }^{34,51}$, however, complex (2) shows a value 0.81 B.M. which is well below the spin only value (1.73 B.M.), indicating that, spin - exchange interactions take place between the copper(II) ions through acetate group in an square planar geometry ${ }^{34,51}$. Nickel(II) complex (6) gives 2.86 B.M., confirmed $\mathrm{t}_{2} \mathrm{~g}^{6} \mathrm{eg}^{2}$ electronic configuration with two unpaired electrons in an octahedral Ni(II) complex ${ }^{34,52}$. Cobalt(II) complex (7) and manganese(II) complex (8) show values 3.4 and 4.9 B.M., indicating high spin octahedral structure ${ }^{34,50}$. Thalium(I) complex (13) gives 2.19 B.M., indicating an octahedral structure. Iron(III) complex (14) and chromium(III) complex (15) show values 5.96 and 3.94 B.M., indicating high spin octahedral structure ${ }^{34,53}$. Zinc(II) complex (9), cadmium(II) complex (10), uranyl complex (11), zirconyl(II) complex (16), calcium(II) complex (17), strontium(II) complex (18) and silver(I) complex (19) show diamagnetic values.

## Electronic spectra

The electronic spectral data for the ligand and its metal complexes in DMF solution are summarized in Table (3). The ligand in DMF solution shows three bands at $388 \mathrm{~nm}\left(\varepsilon=9.36 \times 10^{-3} \mathrm{~mol}^{-1} \mathrm{~cm}^{-1}\right), 319 \mathrm{~nm}(\varepsilon=$ $\left.7.69 \times 10^{-3} \mathrm{~mol}^{-1} \mathrm{~cm}^{-1}\right)$ and $255 \mathrm{~nm}\left(\varepsilon=6.15 \times 10^{-3} \mathrm{~mol}^{-1} \mathrm{~cm}^{-1}\right)$, which may be assigned to the $\mathrm{n} \rightarrow \pi^{*}$ and $\pi \rightarrow \pi^{*}$ transitions respectively ${ }^{54}$. Copper(II) complexes (3), (4) and (5) show bands in the $265-255,324-318$ and 390 385 nm ranges, these bands are due to intraligand transitions, however, the bands appear in the $524-505,584-$ 576 and $649-640 \mathrm{~nm}$ ranges are assigned to $\mathrm{O} \rightarrow \mathrm{Cu}$ charge transfer, ${ }^{2} \mathrm{~B}_{1} \rightarrow{ }^{2} \mathrm{E}$ and ${ }^{2} \mathrm{~B}_{1} \rightarrow^{2} \mathrm{~B}_{2}$ transitions, indicating a distorted tetragonal octahedral structure ${ }^{27,55,56}$. However, cu(II) complex (2) shows bands at 255, 321 and 389 nm , these bands are within the ligand and bands at 490,520 and 580 nm are corresponding to ${ }^{2} \mathrm{~B}_{1 \mathrm{~g}} \rightarrow^{2} \mathrm{~B}_{2 \mathrm{~g}},{ }^{2} \mathrm{~B}_{1 \mathrm{~g}} \rightarrow{ }^{2} \mathrm{E}_{\mathrm{g}}$ and ${ }^{2} \mathrm{~B}_{1 g} \rightarrow{ }^{2} \mathrm{~A}_{1 g}$ respectively, suggesting a square planar geometry ${ }^{57}, 58$. Nickel(II) complex (6) shows bands at 260 , $315,380,490,625$ and 875 nm respectively, the first three bands are within the ligand and the other three bands are attributable to ${ }^{3} \mathrm{~A}_{2 \mathrm{~g}}(\mathrm{~F}) \rightarrow{ }^{3} \mathrm{~T}_{1 \mathrm{~g}}(\mathrm{P})\left(v_{3}\right),{ }^{3} \mathrm{~A}_{2 \mathrm{~g}}(\mathrm{~F}) \rightarrow{ }^{3} \mathrm{~T}_{1 \mathrm{~g}}(\mathrm{~F})\left(\mathrm{v}_{2}\right)$ and ${ }^{3} \mathrm{~A}_{2 \mathrm{~g}}(\mathrm{~F}) \rightarrow{ }^{3} \mathrm{~T}_{2 \mathrm{~g}}(\mathrm{~F})\left(v_{1}\right)$ transitions respectively, indicating an octahedral $\mathrm{Ni}($ II $)$ complex ${ }^{27,59}$. The $v_{2} / v_{1}$ ratio for the complex is 1.4 , which is less than the usual range of $1.5-1.75$, indicating a distorted octahedral Ni (II) complex ${ }^{27,60}$. Cobalt(II) complex (7) shows bands at 250, 321, 390,550 and 650 nm , the first three bands are within the ligand and the other bands are assigned to ${ }^{4} \mathrm{~T}_{1 \mathrm{~g}}(\mathrm{~F}) \rightarrow{ }^{4} \mathrm{~A}_{2 \mathrm{~g}}$ and ${ }^{4} \mathrm{~T}_{1 \mathrm{~g}}(\mathrm{~F}) \rightarrow{ }^{4} \mathrm{~T}_{2 \mathrm{~g}}(\mathrm{~F})$ transitions respectively, corresponding to high spin $\mathrm{Co}(\mathrm{II})$ octahedral complexes ${ }^{6{ }^{61}}$. Manganese(II) complex (8) shows bands at 265, 315, 375, 465, 510 and 605 nm , respectively, the first three bands
are within the ligand, however, the other bands are corresponding to ${ }^{6} \mathrm{~A}_{1 g} \rightarrow{ }^{4} \mathrm{E}_{\mathrm{g}},{ }^{6} \mathrm{~A}_{1 \mathrm{~g}} \rightarrow{ }^{4} \mathrm{~T}_{2 \mathrm{~g}}$ and ${ }^{6} \mathrm{~A}_{1 g} \rightarrow{ }^{4} \mathrm{~T}_{1 g}$ transitions which are compatible to an octahedral geometry around the Mn (II) ion ${ }^{62}$. Tl (I) complex (13) gave bands at 265,310 and 350 nm , respectively. These bands are due to intraligand transitions since these bands appear almost in the spectrum of the ligand, additional weak band appears at 380 nm , which may be assigned to the ${ }^{1} \mathrm{~S}_{0} \rightarrow{ }^{3} \mathrm{P}_{1}$ transition of $\mathrm{Tl}(\mathrm{I})$ complex ${ }^{63}$. Iron(III) complex (14) shows bands at $265,315,390,450$ and 650 nm respectively, the first three bands are within the ligand while the other bands are due to charge transfer and ${ }^{6} \mathrm{~A}_{1} \rightarrow{ }^{4} \mathrm{~T}_{1}$ transitions, suggesting distorted octahedral geometry around the iron(III) ion ${ }^{44,64}$. While chromium(III) complex (15) shows bands at $270,320,380,440,530$ and 630 nm respectively. The first three bands are assigned to ${ }^{4} \mathrm{~A}_{2 \mathrm{~g}} \rightarrow{ }^{4} \mathrm{~T}_{1 g}(\mathrm{~F})$, ${ }^{4} \mathrm{~A}_{2 \mathrm{~g}} \rightarrow{ }^{4} \mathrm{~T}_{2 \mathrm{~g}}$ and ${ }^{4} \mathrm{~A}_{2 g} \rightarrow{ }^{2} \mathrm{~T}_{2 \mathrm{~g}}$ transitions respectively, indicating octahedral structure around the $\mathrm{Cr}($ III $)$ ion ${ }^{65},{ }^{66}$. Zinc(II) complex (9), cadmium(II) complex (10), uranyl(II) complex (11), mercury(II) complex (12), zirconyl(II) complex (16), calcium(II) complex (17), strontium(II) complex (18) and silver(I) complex (19) show three bands in the $270-255,320-310$ and $390-375 \mathrm{~nm}$ ranges, which are assigned to intraligand transitions.

## Electron Spin Resonance (ESR)

The ESR spectral data for complexes (2), (3), (5), (7), (8) and (14) are presented in Table 4.The spectra of copper(II) complexes (2), (3) and (5) are characteristic of species, $\mathrm{d}^{9}$ configuration and having axial type of a $\mathrm{d}_{(\mathrm{x} 2-\mathrm{y})}$ ground state which is the most common for copper(II) complexes ${ }^{67,68}$. The complexes show $\mathrm{g}_{\|}>\mathrm{g}_{\perp}>2.0023$, indicating square planar or octahedral geometry around copper(II) ion ${ }^{69,}{ }^{70}$. The g-values are related by the expression ${ }^{69,71}, \mathrm{G}=\left(\mathrm{g}_{\|}-2\right) /\left(\mathrm{g}_{\perp}-2\right)$, if $\mathrm{G}>4.0$, then, local tetragonal axes are aligned parallel or only slightly misaligned, if $\mathrm{G}<4.0$, the significant exchange coupling is present. Complexes (2) and (5) show values 3.71 and 3.86 indicating spin - exchange interactions take place between copper(II) ions through acetate group (2) or hydrogen bondings (5). This phenomenon is further confirmed by magnetic moments ( 0.81 and 1.68 B.M. respectively). However, complex (3) shows 4.0 indicating tetragonal axes are present in this complex. Also, the $\mathrm{g}_{\|} / \mathrm{A}_{\|}$values considered as diagnostic of stereochemistry ${ }^{72}$, in the range reported for square planar complexes are 105 to $135 \mathrm{~cm}^{-1}$ and for tetragonal distorted octahedral complexes 150 to $250 \mathrm{~cm}^{-1}$. The $\mathrm{g}_{\|} / \mathrm{A}_{\|}$values lie just within the range expected for the complexes (Table 4). The g - value of the copper(II) complexes with a ${ }^{2} \mathrm{~B}_{1 \mathrm{~g}}$ ground state ( $\mathrm{g}_{\|}>\mathrm{g}_{\perp}$ ) may be expressed [73] by
$\mathrm{g}_{\|}=2.002-\left(8 \mathrm{k}_{\|}^{2} \lambda_{\mathrm{o}} / \mathrm{E}_{\mathrm{xy}}\right)$.
$\mathrm{g}_{\perp}=2.002-\left(2 \mathrm{k}_{\perp}^{2} \lambda_{\mathrm{o}} / \mathrm{E}_{\mathrm{xz}}\right)$
where $\mathrm{k}_{\|}$and $\mathrm{k}_{\perp}$ are the parallel and perpendicular components respectively of the orbital reduction factor $(\mathrm{K}), \lambda^{\circ}$ is the spin - orbit coupling constant for the free copper, $\mathrm{E}_{\mathrm{xy}}$ and $\mathrm{E}_{\mathrm{xz}}$ are the electron transition energies of
${ }^{2} \mathrm{~B}_{1 \mathrm{~g}} \rightarrow^{2} \mathrm{~B}_{2 \mathrm{~g}}$ and ${ }^{2} \mathrm{~B}_{1 \mathrm{~g}} \rightarrow{ }^{2} \mathrm{E}_{\mathrm{g}}$. From the above relations, the orbital reduction factors ( $\mathrm{K}_{\|}, \mathrm{K}_{\perp}, \mathrm{K}$ ), which are a measure of covalency ${ }^{73}$ can be calculated. For an ionic environment $\mathrm{K}=1$ and for a covalent environment $\mathrm{K}<1$. The lower the value of k , the greater is the covalency
$\mathrm{K}_{\perp}^{2}=\left(\mathrm{g}_{\perp}-2.002\right) \mathrm{E}_{\mathrm{xz}} / 2 \lambda_{0}$.
$\mathrm{K}_{\|}^{2}=\left(\mathrm{g}_{\|}-2.002\right) \quad \mathrm{E}_{\mathrm{xy}} / 8 \lambda_{0} \ldots$
$K^{2}=\left(K_{\|}^{2}+2 K^{2}{ }_{\perp}\right) / 3$..
K (Table 4), for the copper(II) complexes (2), (3) and (5), indicating covalent bond character ${ }^{48,74}$. Kivelson and Neiman ${ }^{75}$ noted that, for ionic environment $g_{\|} \geq 2.3$ and for a covalent environment $g_{\|}<2.3$. Theoretical work by Smith ${ }^{76}$ seems to confirm this view. The $g$ - values reported here (Table 4) show considerable covalent bond character ${ }^{48}$. Also, the in-plane $\delta$ - covalency parameter, $\alpha^{2}(\mathrm{Cu})$ was calculated by
$\alpha^{2}(\mathrm{Cu})=\left(\mathrm{A}_{\|} / 0.036\right)+\left(\mathrm{g}_{\|}-2.002\right)+3 / 7\left(\mathrm{~g}_{\perp}-2.002\right)+0.04$.
The calculated values (Table 4) suggest a covalent bonding ${ }^{45,48,74}$. The in-plane and out of- plane $\pi$ - bonding coefficients $B_{1}{ }^{2}$ and $B^{2}$ respectively, are dependent upon the values of $E_{x y}$ and $E_{x z}$ in the following equations ${ }^{69}$. $\alpha^{2} \beta^{2}=\left(g_{\perp}-2.002\right) \quad E_{x y} / 2 \lambda_{0}$

$$
\alpha^{2} \beta_{1}^{2}=\left(g_{\|}-2.002\right) \quad \mathrm{E}_{\mathrm{xz}} / 8 \lambda_{0}
$$

in this work, the complexes show $\beta_{1}{ }^{2}$ values 0.78 and 0.72 (2) and (3), indicating a moderate degree of covalency in the in-plane $\pi$-bonding, however, complex (5) shows 1.02 indicating ionic character ${ }^{74,77}$. While $\beta^{2}$ for complexes (3) and (5) are 0.87 and 0.82 respectively, indicating covalent bonding character out of- plane $\pi$ - bonding, however, complex (2) shows 1.1, indicating ionic character of the out of- plane ${ }^{74,77}$. It is possible to calculate approximate orbital populations for s, p or dorbitals ${ }^{78}$ by

$A_{\perp}=A_{i s o}+B\left[1 \pm(7 / 2) \quad g_{\perp}\right]$.
$\mathrm{a}^{2}{ }_{\mathrm{s}}=\mathrm{A}_{\mathrm{iso}} / \mathrm{A}^{\circ} \quad, \mathrm{a}_{\mathrm{p}, \mathrm{d}}^{2}=2 \mathrm{~B} / 2 \mathrm{~B}^{\circ}$
where $\mathrm{A}^{\circ}$ and $2 \mathrm{~B}^{\circ}$ are the calculated dipolar coupling for unit occupancy of s and d orbitals respectively. The calculated orbital publications for the copper(II) complexes (2), (3) and (5), (Table 4), indicate a $\mathrm{d}_{(x 2-y 2)}$ ground state ${ }^{42}$. The ESR spectrum for complex (2) shows seven lines in the low and high field regions with some lines in the centre field region were also observed. This is a characteristic of the triplet state for a dimmer species. The zero field splitting parameter (D) for the parallel components of the dimmer complex (2) was estimated from the spectrum and is equal to 500 G . The distance between the two copper centers was calculated using the following equation ${ }^{48,79}$
$\mathrm{D}={ }^{3 \mu} \mathrm{~B} / 2 \mathrm{R}^{3}\left(3 \cos ^{2} \theta-1\right)$
Where ${ }^{3 \mu} B$ is the magnetic moment of the electron and $R$, is the distance ( $\mathrm{A}^{\circ}$ ) between the electrons. For parallel component (D), $\theta=0$, by substitute in equation (12), $D$ is equal to ${ }^{3 \mu} B / R^{3}$ for a bi-radical system in the triplet state, it is found that, D for the parallel components is equal to 402 G and the distance between the two radicals is equal to $5.2 \mathrm{~A}^{\circ}$. From these data, the distance between the two copper(II) centers was calculated and is equal to $4.2 \mathrm{~A}^{\circ}$. This value is close to that for a dimeric copper(II) compound in the triplet -state ${ }^{48,80}$. Cobalt(II) complex (7), manganese(II) complex (8) and iron(III) complex (14) show isotropic spectra with values 2.1, 2.008 and 2.09, respectively confirmed octahedral structure ${ }^{48,68}$.

## Thermal Analyses [DTA and TGA]

Since the IR spectra indicate the presence of water molecules, thermal analyses (DTA and TGA) were carried out to a certain their nature. The thermal curves in the temperature $27-800^{\circ} \mathrm{C}$ range for complexes (2), (5), (7) and (9) are thermally stable up to $35^{\circ} \mathrm{C}$. Dehydration is characterized by endothermic peaks within the temperature $70-90^{\circ} \mathrm{C}$ range, corresponding to the loss of hydrated water molecules ${ }^{81,82}$. The decomposition step for complex (2) occurred at $90^{\circ} \mathrm{C}$ with $7.33 \%$ weight loss (Calc. $6.92 \%$ ), which could be due to the elimination of $3 \mathrm{H}_{2} \mathrm{O}$. Another thermal decomposition at 175 and $257^{\circ} \mathrm{C}$ with $29.32 \%$ weight loss (Calc. $30.6 \%$ ), which could be due to the loss of $\mathrm{C}_{4} \mathrm{H}_{12} \mathrm{~N}_{10}$ moiety. Also, the complex shows two endothermic peaks at 263 and $321^{\circ} \mathrm{C}$ with $24.2 \%$ weight loss (Calc. 24.48\%), corresponding to the loss of two acetate groups. Endothermic peak observed at $335^{\circ} \mathrm{C}$
gwith no weight loss may be due to melting point. Finally, the complex shows exothermic peaks in the 400 $-600^{\circ} \mathrm{C}$ range, corresponding to oxidative thermal decomposition which proceeds slowly with final residue at $660^{\circ} \mathrm{C}$, assigned to $\mathrm{CuO}^{81}$. Complex (5) shows endothermic peak at $70^{\circ} \mathrm{C}$, with $3.3 \%$ weight loss (Calc. $3.2 \%$ ), due to one hydrated water, however, the peak observed at $140^{\circ} \mathrm{C}$ with $7.2 \%$ weight loss (Calc. $6.69 \%$ ), assigned to two coordinated water molecules, $\mathrm{C}_{4} \mathrm{H}_{12} \mathrm{~N}_{10}$ moiety decomposed at 180 and $215^{\circ} \mathrm{C}$ with $40.67 \%$ weight loss (Calc. $39.84 \%$ ). The endothermic peak observed at $315^{\circ} \mathrm{C}$ may be assigned to the melting point. Oxidative thermal decomposition occurs in the $350-650^{\circ} \mathrm{C}$ range with exothermic peaks, leaving $\mathrm{CuO} 26.27 \%$ weight loss (Calc. $26.32 \%)^{83}$. Complex (7) shows endothermic peak at $70^{\circ} \mathrm{C}$ with $11.0 \%$ weight loss (Calc. $11.1 \%$ ) due to three hydrated water molecules, however, endothermic peak observed at $135^{\circ} \mathrm{C}$ with $7.8 \%$ weight loss (Calc. $8.3 \%$ ), due to the loss of two coordinated water. However, the endothermic peak appears at $170^{\circ} \mathrm{C}$ with $22.8 \%$ weight loss (Calc. $23.1 \%$ ) is assigned to $\mathrm{C}_{2} \mathrm{H}_{6} \mathrm{~N}_{5}$ moiety. The endothermic peak observed at $237^{\circ} \mathrm{C}$ with $35.1 \%$ weight loss (Calc. $35.43 \%$ ) is due to the loss of two coordinated groups. The endothermic peak observed at $370^{\circ} \mathrm{C}$ may be assigned to the melting point. Oxidative thermal decomposition occurs in the $400-650^{\circ} \mathrm{C}$ range with exothermic peaks, leaving CoO with $34.2 \%$ weight loss (Calc. $34.88 \%)^{83}$. Finally, complex (9) shows endothermic peak at $150^{\circ} \mathrm{C}$ with $8.4 \%$ weight loss (Calc. $8.2 \%$ ) due to the loss of two coordinated water molecules, another endothermic peak is appeared at $213^{\circ} \mathrm{C}$ with $24.37 \%$ weight loss (Calc. $24.74 \%$ ) is assigned to the loss of $\mathrm{C}_{2} \mathrm{H}_{6} \mathrm{O}_{5}$ moiety, however, the acetate group lost as endothermic peak at $363^{\circ} \mathrm{C}$ with $39.49 \%$ weight loss (Calc. $38.81 \%$ ). The endothermic peak appears at $413^{\circ} \mathrm{C}$ may be assigned to the melting point, oxidative thermal decomposition occurs in the $430-590^{\circ} \mathrm{C}$ range with exothermic peaks, leaving ZnO at $590^{\circ} \mathrm{C}$ with $43.6 \%$ weight loss (Calc. $\left.43.55 \%\right)^{83}$.

## Biological activity

The biological activity of the ligand, (1) and its metal complexes (2), (4), (9),(10) and (13) were evaluated against HEPG- 2 cell line. In this study, we try to know the chemotherapeutic activity of the tested complexes by comparing them with the standard drug (IMURAN® (azathioprine)). The treatment of the different complexes in DMSO showed similar effects in the tumoral cell line used as it was previously reported ${ }^{84}$. The solvent (dimethyl sulphoxide, DMSO) shows no effect in cell growth. The ligand (1), shows a weak inhibition effect at ranges of concentration used, however, the complexes showed moderate effect against HEPG- 2. The obtained data indicate, the surviving fraction ratio against HEPG- 2 tumor cell line increasing with the increase of the concentration in the range of the tested concentration. Also, the $\mathrm{Cd}(\mathrm{II})$ complex (10) shows a high potency of around $65 \%$ inhibition at $25 \mathrm{Mg} / \mathrm{m} \ell$ against HEPG- 2 , compared with a standard drug ${ }^{83}$. This can be explained because cadmium(II) binds to DNA. It seems that, change the anion and the nature of the metal ion has effect on the biological behavior, due to alter binding ability of the DNA binding, so testing of different complexes is very interesting from this point of view. Chemotheraputic activity of the complexes may be attributed to the central metal atom which was explained by Tweedy's chelation theory ${ }^{84,85}$. Also, the positive charge of the metal increases the acidity of coordinated ligand that bears protons, leading to stronger hydrogen bonds which enhance the biological activity ${ }^{86-88}$. Moreover, Gaetke and Chow had reported that, metal has been suggested to facilitate oxidated tissue injury through a freeradical mediated pathway analogous to the Fenton reaction ${ }^{89}$. By applying the ESR-trapping technique, evidence for metal - mediated hydroxyl radical formation in vivo has been obtained ${ }^{72}$. ROS are produced through a Fenton-type reaction as follows:

```
LM(II) + + H2\mp@subsup{O}{2}{}}
LM(I) + H2O2 }\mp@subsup{\textrm{O}}{2}{
```

Where L , organic ligand

Also, metal could act as a double-edged, sword by inducing DNA damage and also by inhibiting their repair ${ }^{90}$. The OH radicals react with DNA sugars and bases and the most significant and well-characterized of the OH reactions is hydrogen atom abstraction from the $\mathrm{C}_{4}$ on the deoxyribo usenit to yield sugar radicals with subsequent $\beta$ elimination,
Scheme 2. By this mechanism strand breakage occurs as well as the release of the free bases. Another form of attack on the DNA bases is by solvated electrons, probably via a similar reaction to those discussed below for the direct effects of radiation on DNA ${ }^{90}$ Figure 3.

Scheme (2)

In the ranges of concentrations used, the obtained data indicate that, the order of chemotherapeutic effect. At concentrations $25,12.5$ and $6.5 \mu \mathrm{~g}$ is standard $>\mathrm{Cd}$ (II) complex (10) $>\mathrm{Cu}$ (II) complex (4) $>\mathrm{Cu}$ (II) complex (2) $>$ Tl (I) complex (13) $>\mathrm{Zn}$ (II) complex (9), however, at concentration $3.125 \mu \mathrm{~g}$ is Cd (II) complex (10) $>\mathrm{Cu}(\mathrm{II})$ complex (4) $>$ standard $>\mathrm{Cu}($ II $)$ complex (2) $>\mathrm{Tl}(\mathrm{I})$ complex (13) $>\mathrm{Zn}(\mathrm{II})$ complex (9) and at $1.56 \mu \mathrm{~g}$ is $\mathrm{Tl}(\mathrm{I})$ complex (13) $>\mathrm{Cd}$ (II) complex (10) $>\mathrm{Zn}$ (II) complex (9) $>$ standard $>\mathrm{Cu}$ (II) complex (2) $=\mathrm{Cu}$ (II) complex (4) Although, the complexes are octahedral structures and have the same anions, the variable activity of the complexes may be used to oxidation - reduction potentials. The chemotherapeutic effect of a standard drug and metal complexes in the ranges of concentrations used against human HEPG- 2 cancer cell line are shown in Figure 4.

Abdou Saad El-Tabl et al /Int.J.ChemTech Res.2013,5(1)

Chemotherapeutic effect of complexes (2), (4), (9), (10) and (13) against HEPG - 2 liver cell line at $25 \mu \mathrm{~g}$
