Anti-Synchronization of Brusselator Chemical Reaction Systems via Integral Sliding Mode Control

Sundarapandian Vaidyanathan*

R & D Centre, Vel Tech University, Avadi, Chennai, Tamil Nadu, India

Abstract: In the 1970s, nonlinear oscillations and bifurcations were discovered first by modelling and then by experiments for the autocatalytic Brusselators and the Belousov-Zhabotinsky (BZ) chemical reaction. The autocatalytic chemical reaction phenomenon plays a vital role for the breakdown of the stability of the thermodynamical branch. This research work investigates the dynamics and qualitative properties of the autocatalytic Brusselator chemical reaction. Then this work discusses the global anti-synchronization of the identical Brusselator chemical reaction systems via integral sliding mode control (ISMC). The main global anti-synchronization result for the Brusselator chemical reaction systems is established using Lyapunov stability theory. MATLAB plots have been shown to illustrate all the main results discussed in this work.

Keywords: Chaos, chaotic systems, chemical reactor, Brusselator, chemical engineering, sliding mode control, anti-synchronization, nonlinear oscillations, chaos control, stability.

1. Introduction

A dynamical system is called *chaotic* if it satisfies the three properties: boundedness, infinite recurrence and sensitive dependence on initial conditions [1-2]. Chaos theory investigates the qualitative and numerical study of unstable aperiodic behaviour in deterministic nonlinear dynamical systems.

In 1963, Lorenz [3] discovered a 3-D chaotic system when he was studying a 3-D weather model for atmospheric convection. After a decade, Rössler [4] discovered a 3-D chaotic system, which was constructed during the study of a chemical reaction. These classical chaotic systems paved the way to the discovery of many 3-D chaotic systems such as Arneodo system [5], Sprott systems [6], Chen system [7], Lü-Chen system [8], Cai system [9], Tigan system [10], etc. Many new chaotic systems have been also discovered in the recent years like Sundarapandian systems [11, 12], Vaidyanathan systems [13-43], Pehlivan system [44], Pham system [45], etc.

Recently, there is significant result in the chaos literature in the synchronization of physical and chemical systems. A pair of systems called master and slave systems are considered for the synchronization process and the design goal of anti-synchronization is to device a feedback mechanism so that the state trajectories of the master and slave systems are equal in magnitude and opposite in sign asymptotically. Because of the butterfly effect which causes exponential divergence of two trajectories of the system starting from nearby initial conditions, the anti-synchronization of chaotic systems is seemingly a challenging research problem.

In control theory, active control method is used when the parameters are available for measurement [46-65]. Adaptive control is a popular control technique used for stabilizing systems when the system parameters are unknown [66-80]. There are also other popular methods available for control and synchronization of systems such as backstepping control method [81-87], sliding mode control method [88-100], intelligent control [101-110], etc.

Recently, chaos theory is found to have important applications in several areas such as chemistry [111-128], biology [129-160], memristors [161-163], electrical circuits [164], etc.

In the 1970s, nonlinear oscillations and bifurcations were discovered first by modelling and then by experiments for the autocatalytic Brusselators and the Belousov-Zhabotinsky chemical reaction [165-166]. The autocatalytic chemical reaction phenomenon plays a vital role for the breakdown of the stability of the thermodynamical branch.

A simple chemical model that exhibits complex dynamics is the Brusselator model, which is an example of an autocatalytic oscillating chemical reaction [167]. This model could present the limit cycle, Hopf bifurcation and also the chaotic behaviour when a certain sinusoidal force acts on the system. This force could be created by the heat convection, microwaves etc., that its behaviour is sinusoidal with a small intensity.

This paper describes the modelling and properties of the Brusselator dynamics. This paper also derives new results of anti-synchronization design for the identical Brusselator chemical reaction systems via integral sliding mode control [168]. The main control result is established using Lyapunov stability theory [169].

2. Brusselator Chemical Reaction Model

The mechanism for the classical Brusselator chemical model [167] is given as follows:

$A \xrightarrow{k_1} X$	(1)
$B + X \xrightarrow{k_2} Y + D$	(2)
$2X + Y \xrightarrow{k_3} 3X$	(3)
$X \xrightarrow{k_4} E$	(4)

The Brusselator chemical reaction model describes a chemical system that converts a reactant A to a final product E through four steps and four intermediate species, X, B, Y and D. The steps (2) and (3) are bimolecular, and autocatalytic trimolecular reactions respectively. Based on the mechanism of Brusselator reaction, product E is resulted from species X in step (4). In addition, species X is the result of steps (1) and (3). These relationships could show the sensitivity to initial conditions.

We denote the concentrations of A, B, D, E, X, and Y by [A], [B], [D], [E], [X], and [Y], respectively. Then the evolutions of the concentrations of the species as a function of the time t using mass action law are given as follows:

$$\frac{d[A]}{dt} = -k_1[A] \tag{5}$$

$$\frac{d[B]}{dt} = -k_2[B][X] \tag{6}$$

$$\frac{d[D]}{dt} = k_2[B][X] \tag{7}$$

$$\frac{d[E]}{dt} = k_4 [X] \tag{8}$$

$$\frac{d[X]}{dt} = k_1[A] - k_2[B][X] + k_3[X]^2[Y] - k_4[X]$$
(9)

$$\frac{d[Y]}{dt} = k_2 [B] [X] - k_3 [X]^2 [Y]$$
⁽¹⁰⁾

where k_j , (j = 1, 2, 3, 4) is the reaction rate and represented in units of $(mole / l \cdot s)^{-1}$.

Since the species D and E do not influence others, we ignore (7) and (8). Moreover, for simplicity, we suppose that [A] and [B] are maintained constant, *i.e.* [A] = a and [B] = b, where a, b > 0, and all reaction rates k_i , (j = 1, 2, 3, 4) are set equal to unity.

Thus, the ordinary differential equations that describe the Brusselator chemical reaction are as follows:

$$\begin{cases}
\frac{d[X]}{dt} = a + [X]^2 [Y] - (b+1)[X] \\
\frac{d[Y]}{dt} = b[X] - [X]^2 [Y]
\end{cases}$$
(11)

To simplify the notation, we define x = [X] and y = [Y].

(1[17]

Then we can represent the Brusselator chemical reaction given in (11) in a compact form as follows. $(\dot{r} - a + r^2 v - (b + 1)r)$

$$\begin{cases} x = a + x \ y - (b+1)x \\ \dot{y} = bx - x^2 y \end{cases}$$
(12)

Thus, the unique equilibrium point of (12) is easily obtained as E_0 : $(x, y) = \left(a, \frac{b}{a}\right)$.

The Jacobian matrix of (12) at the equilibrium point E_0 is obtained as

$$J_0 = J(E_0) = \begin{bmatrix} b-1 & a^2 \\ -b & -a^2 \end{bmatrix}$$
(13)

The characteristic equation of the Jacobian matrix J_0 is easily obtained as

$$\lambda^{2} + (a^{2} - b + 1)\lambda + a^{2} = 0$$
(14)

By Routh's stability theorem, the equilibrium point E_0 is stable if and only if

$$a^2 - b^2 + 1 > 0$$
 or $b < a^2 + 1$ (15)

Also, the equilibrium point E_0 is unstable if

$$a^2 - b^2 + 1 < 0 \text{ or } b > a^2 + 1$$
 (16)

Therefore, for $b > a^2 + 1$, the Brusselator chemical model (12) has a limit cycle.

Assuming $b = a^2 + 1$, the Brusselator chemical model (12) exhibits *Hopf bifurcation*.

For numerical simulations, we take a = 1 mole / l, b = 3 mole / l where $b > a^2 + 1$.

We take the initial values of the concentrations x and y as x(0) = 0.1 mole/l, y(0) = 0.5 mole/l.

Figure 1 shows the limit cycle of the Brusselator chemical reaction system (12).

Figure 1. Limit cycle of the Brusselator chemical reaction system

3. Anti-Synchronization of Identical Brusselator Chemical Reaction Systems

In this section, we use integral sliding mode control to achieve global and asymptotic antisynchronization of the identical Brusselator chemical reaction systems. We use Lyapunov stability theory to prove the main result derived in this section for the Brusselator chemical reaction systems.

As the master system, we consider the Brusselator chemical reaction system given by

$$\begin{cases} \dot{x}_1 = a + x_1^2 y_1 - (b+1)x_1 \\ \dot{y}_1 = bx_1 - x_1^2 y_1 \end{cases}$$
(17)

As the slave system, we consider the Brusselator chemical reaction system with controls given by

$$\begin{cases} \dot{x}_2 = a + x_2^2 y_2 - (b+1)x_2 + u_x \\ \dot{y}_2 = bx_2 - x_2^2 y_2 + u_y \end{cases}$$
(18)

The anti-synchronization error between the Brusselator reaction systems (17) and (18) is defined by

$$\begin{cases}
e_x = x_2 + x_1 \\
e_y = y_2 + y_1
\end{cases}$$
(19)

We note that the errors $e_x \to 0$ and $e_y \to 0$ if and only if $x_2 \to -x_1$ and $y_2 \to -y_1$. Thus, when the identical Brusselator chemical reaction systems (17) and (18) are anti-synchronized, their states will be equal in magnitude, but opposite in sign.

The error dynamics is obtained as

$$\begin{cases} \dot{e}_x = 2a + x_2^2 y_2 + x_1^2 y_1 - (b+1)e_x + u_x \\ \dot{e}_y = be_x - x_2^2 y_2 - x_1^2 y_1 + u_y \end{cases}$$
(20)

Based on the sliding mode control theory [168], the integral sliding surface of each error variable is defined as follows:

$$\begin{cases} s_x = \left[\frac{d}{dt} + \lambda_x\right] = \left[\int_0^t e_x(\tau)d\tau\right] & e_x + \lambda_x \int_0^t e_x(\tau)d\tau \\ s_y = \left[\frac{d}{dt} + \lambda_y\right] = \left[\int_0^t e_y(\tau)d\tau\right] & e_y + \lambda_y \int_0^t e_y(\tau)d\tau \end{cases}$$
(21)

The derivative of each equation in (21) yields

$$\begin{cases} \dot{s}_x = \dot{e}_x + \lambda_x e_x \\ \dot{s}_y = \dot{e}_y + \lambda_y e_y \end{cases}$$
(22)

The Hurwitz condition is satisfied if λ_x , λ_y are positive constants.

Based on the exponential reaching law [168], we set

$$\begin{cases} \dot{s}_x = -\eta_x \operatorname{sgn}(s_x) - k_x s_x \\ \dot{s}_y = -\eta_y \operatorname{sgn}(s_y) - k_y s_y \end{cases}$$
(23)

Comparing equations (22) and (23), we get

$$\begin{cases} \dot{e}_x + \lambda_x e_x & -\eta_x = \operatorname{sgn}(s_x) - k_x s_x \\ \dot{e}_y + \lambda_y e_y & -\eta_y = \operatorname{sgn}(s_y) - k_y s_y \end{cases}$$
(24)

Using Eq. (20), we can rewrite Eq. (24) as follows:

$$\begin{cases} 2a + x_{2}^{2}y_{2} + x_{1}^{2}y_{1} - (b+1)e_{x} + u_{x} + \lambda_{x}e_{x} & -\eta_{x} \operatorname{sgn}(s_{x}) - k_{x}s_{x} \\ be_{x} - x_{2}^{2}y_{2} - x_{1}^{2}y_{1} + u_{y} + \lambda_{y}e_{y} & -\eta_{y} \operatorname{sgn}(s_{y}) - k_{y}s_{y} \end{cases}$$
(25)

From Eq. (25), the control laws are obtained as follows:

$$\begin{cases} u_x = -2a - x_2^2 y_2 - x_1^2 y_1 + (b+1)e_x - \lambda_x e_x - \eta_x \operatorname{sgn}(s_x) - k_x s_x \\ u_y = -be_x + x_2^2 y_2 + x_1^2 y_1 - \lambda_y e_y - \eta_y \operatorname{sgn}(s_y) - k_y s_y \end{cases}$$
(26)

Next, we state and prove the main result of this section.

Theorem 1. The Brusselator chemical reaction systems (17) and (18) are globally and asymptotically anti-synchronized for all initial conditions by the integral sliding mode control law (26), where the constants $\lambda_x, \lambda_y, \eta_x, \eta_y, k_x, k_y$, are all positive.

Proof. This result is proved using Lyapunov stability theory [169].

We consider the following quadratic Lyapunov function

$$V(s_x, s_y) = \frac{1}{2} \left(s_x^2 + s_y^2 \right)$$
(27)

where s_x, s_y are as defined in (21).

The time-derivative of V is obtained as

$$V = s_x \dot{s}_x + s_y \dot{s}_y \tag{28}$$

Substituting from Eq. (23) into (28), we get

$$\dot{V} = s_x [-\eta_x \operatorname{sgn}(s_x) - k_x s_x] + s_y [-\eta_y \operatorname{sgn}(s_y) - k_y s_y]$$
Simplifying Eq. (29), we obtain
$$(29)$$

$$\dot{V} = -\eta_x \left| s_x \right| - k_x s_x^2 - \eta_y \left| s_y \right| - k_y s_y^2 \tag{30}$$

Since $k_x, k_y > 0$ and η_x, η_y it follows from (30) that \dot{V} is a negative definite function.

Thus, by Lyapunov stability theory [169], it follows that $(s_x, s_y) \rightarrow (0, 0)$ as $t \rightarrow \infty$.

Hence, it is immediate that $(e_x, e_y) \rightarrow (0, 0)$ as $t \rightarrow \infty$.

This completes the proof. \blacksquare

4. Numerical Simulations

We use classical fourth-order Runge-Kutta method in MATLAB with step-size $h = 10^{-8}$ for solving the system of differential equations (17) and (18), when the integral sliding mode controller (26) is implemented.

The parameter values of the Brusselators (17) and (18) are taken as	
a = 1, b = 3	(27)
We take the sliding constants as	
$\lambda_x = \lambda_y = 0.1 = \eta_x = \eta_y = 0.1 = k_x k_y 20$	(28)
We take the initial conditions of the Brusselator chemical reaction system (17) as	
$x_1(0) = 1.4, y_1(0) = 5.8$	(29)
We take the initial conditions of the novel chemical reactor (18) as	
$x_2(0) = 7.5, y_2(0) = 15.2$	(30)
Figures 2-3 shows the anti-synchronization of the Brusselator chemical reaction systems (17) and (18).	

Figure 4 shows the time-history of the anti-synchronization errors e_x, e_y .

Figure 2. Anti-synchronization of the states x_1 and x_2

Figure 3. Anti-synchronization of the states y_1 and y_2

Figure 4. Time-history of the anti-synchronization errors e_x, e_y

5. Conclusions

In this paper, we investigated the dynamics and qualitative properties of the autocatalytic Brusselator chemical reaction. Then we discussed the global anti-synchronization of the identical Brusselator chemical reaction systems via integral sliding mode control (ISMC). The main global anti-synchronization result for the Brusselator chemical reaction systems was established using Lyapunov stability theory. MATLAB plots were shown to illustrate all the main results discussed in this work for the Brusselator chemical system.
